

CS 1428
Fall 2019
Gentry Atkinson
Lab 12

Introduction:

You should be very familiar with functions by now. We have studied calling and defining them over the last few weeks. But let's take a minute to consider what could happen if a function calls itself (or another copy of itself). The intuitive answer is that this would cause an infinite loop of sorts. But this isn't the case if we are careful when crafting our functions. This technique is called recursion.

Every recursive function must have a "**Base Case**", which is some condition which will cause it to return a fixed value. Every call to a recursive function creates a chain of function calls which ends with the Base Case. This final function call then passes a value back up to the function instance which called it. That value is then processed and passed farther up the chain to the next instance of the function. This process continues until every instance of the function has received and returned a value. The first instance terminates last and returns its value to whatever entity called it. Be very careful when creating a recursive function to always include a base case which you know will be reached.

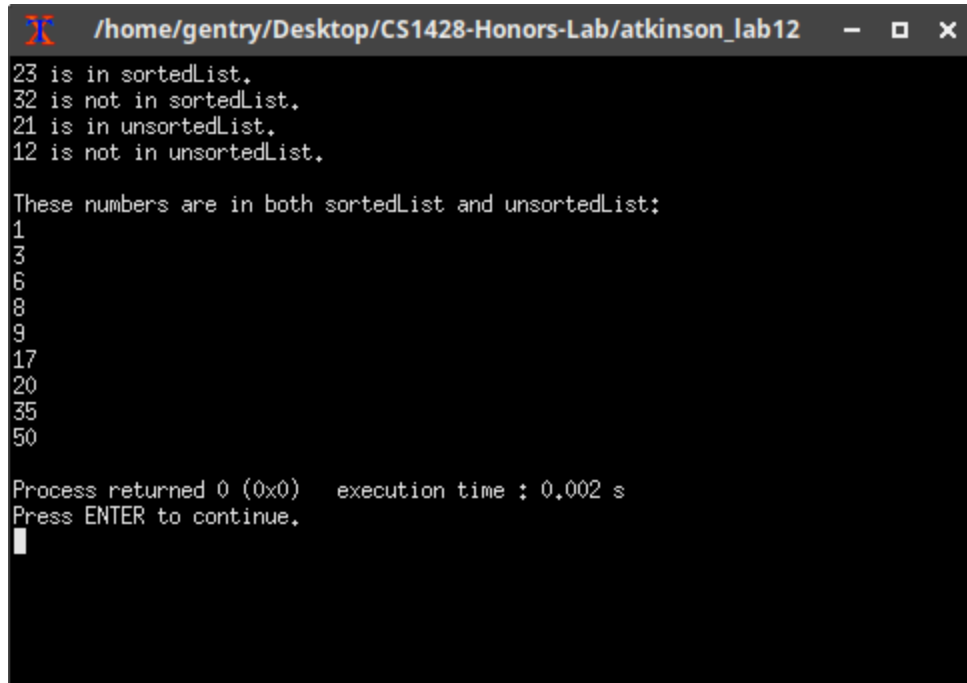

Recursion can be very useful and powerful or very expensive and counter-intuitive. Learning when to use recursion and when to use iteration is part of the process of learning to code.

The purpose of today's lab is to introduce you to recursion.

- 1- Download the starter file `yourName_lab12.cpp` from the TRACS site. Give it an appropriate name.
- 2- Fill in the standard header with your name.
- 3- You have been given partial implementations for two search functions: Binary Search and Sequential Search. Follow the instructions in the comments to fill in two working functions.
- 4- Add four function calls to your main function. Use **the best function** for each call.
 1. Search `sortedList` for the number 23 and print the return with a **cout** statement.
 2. Search `sortedList` for the number 32 and print the return with a **cout** statement.
 3. Search `unsortedList` for the number 21 and print the return with a **cout** statement.
 4. Search `unsortedList` for the number 12 and print the return with a **cout** statement.

5- Add a **for loop** to your main function which iterates an **index i** from 0 to 50 (including 50). The body of this loop should use your two search functions to print every value of **i** that is in **sortedList** and **unsortedList**.

6- Build and run your code. Correct any errors. Your output should look something like this:

A terminal window with a dark background and light-colored text. The window title is "/home/gentry/Desktop/CS1428-Honors-Lab/atkinson_lab12". The output shows a loop from i=0 to i=50. For each i, it checks if i is in sortedList and if i is in unsortedList. The output for i=23 is "23 is in sortedList.", for i=32 is "32 is not in sortedList.", for i=21 is "21 is in unsortedList.", and for i=12 is "12 is not in unsortedList.". Then it prints "These numbers are in both sortedList and unsortedList:" followed by a list of numbers: 1, 3, 6, 8, 9, 17, 20, 35, 50. At the bottom, it says "Process returned 0 (0x0) execution time : 0.002 s" and "Press ENTER to continue." with a cursor on the next line.

```
/home/gentry/Desktop/CS1428-Honors-Lab/atkinson_lab12
23 is in sortedList.
32 is not in sortedList.
21 is in unsortedList.
12 is not in unsortedList.

These numbers are in both sortedList and unsortedList:
1
3
6
8
9
17
20
35
50

Process returned 0 (0x0)   execution time : 0.002 s
Press ENTER to continue.
█
```

7- Submit your .cpp file to TRACS. You can leave when you're done.
